Experiment 4: Fire Tolerant Plants Analysis

Fire-Related Plant Traits Analysis

Total Species with Fire Traits: 2

Fire-Related Traits Analyzed: 3

Fire Risk Assessment Methodology

```
FIRE RISK ASSESSMENT METHODOLOGY

Risk Assessment Criteria:
The fire risk assessment is based on two key fire survival traits:

1. RESPROUTING CAPACITY
   - Ability to regrow from surviving plant parts after fire
   - Indicates rapid post-fire recovery potential
   - Species with 'resprouts' in resprouting_capacity trait

2. POST-FIRE RECRUITMENT
   - Ability to establish new individuals after fire events
   - Indicates long-term population recovery potential
   - Species with 'post_fire_recruitment' (not 'absent') in post_fire_recruitment trait

RISK LEVEL DETERMINATION:

LOW RISK (Green):
- Condition: Can BOTH resprout AND has post-fire recruitment
- Interpretation: Best fire survival strategy with dual protection
- Management: Can withstand frequent burning, suitable for hazard reduction burns

MEDIUM RISK (Orange):
- Condition: Can EITHER resprout OR has post-fire recruitment (only one trait)
- Interpretation: Partial fire survival strategy with limited protection
- Management: Moderate fire tolerance, requires careful burn planning

HIGH RISK (Red):
- Condition: Cannot resprout AND has no post-fire recruitment
- Interpretation: Poor fire survival strategy with minimal protection
- Management: High fire sensitivity, needs protection from frequent burning

APPLICATION FOR HAZARD REDUCTION BURNING:
- Low Risk species/families: Suitable for frequent burning
- Medium Risk species/families: Moderate burning frequency
- High Risk species/families: Minimal burning, focus on protection
